Crashes QGIS or corrupts data:	Copied to github as #: 27075

Description

Using the Identify features tool, I right-click on features and shows the list of layers/features

As you can see in the attached image, some layers have submenu which usually helps to select among overlying features. But in this case, there's only a single entry (and I'm not sure it has the expected label). This is true for the two layers in the image.

All I can say about them is that they are temporary layers but it's also the case for the two at the bottom that have one feature clicked and do not propose submenu
